Write a script to change the created date of an image in a folder, make it random date so that each file gets randomized

To change the creation date of images in a folder to a random date, we can use a Python script that utilizes the `os` and `random` libraries. The script will traverse the folder, select each image file, and set a random creation date for it.

Here's an example script:

```python
import os
import random
import time
from datetime import datetime, timedelta

# Function to generate a random datetime
def get_random_datetime(start_year=2000, end_year=2024):
    # Define start and end dates
    start_date = datetime(start_year, 1, 1)
    end_date = datetime(end_year, 12, 31)

    # Generate a random number of days between the start and end dates
    random_days = random.randint(0, (end_date - start_date).days)

    # Generate a random number of seconds in a day
    random_seconds = random.randint(0, 24 * 60 * 60)

    # Combine both to get a random datetime
    random_date = start_date + timedelta(days=random_days, seconds=random_seconds)
    return random_date

# Function to change the creation date of a file
def change_file_creation_date(file_path, new_date):
    new_timestamp = new_date.timestamp()
    os.utime(file_path, (new_timestamp, new_timestamp))

# Folder containing the images
folder_path = '/path/to/your/folder'

# Iterate over each file in the folder
for filename in os.listdir(folder_path):
    file_path = os.path.join(folder_path, filename)

    # Check if the file is an image (optional: add more extensions if needed)
    if filename.lower().endswith('.jpg', '.jpeg', '.png', '.gif', '.bmp'):
        # Generate a random date
        random_date = get_random_datetime()

        # Change the file's creation date
        change_file_creation_date(file_path, random_date)

        # Print the changes for verification
        print(f"Changed creation date of {filename} to {random_date}")
```

How It Works

1. **`get_random_datetime`**: This function generates a random datetime between two given years.
2. **`change_file_creation_date`**: This function changes the creation date of a given file. In the script, we use `os.utime()` to change the modification and access times. Note that Python does not provide a built-in way to change the creation date directly; this example will work on some systems, but not all.

Usage

1. Replace `'/path/to/your/folder'` with the actual path to the folder containing your images.
2. You can modify the `start_year` and `end_year` in `get_random_datetime` to set the range for random dates.
3. The script iterates through each image file in the specified folder and changes its creation date to a random date.

Note: Changing the creation date of files might not be supported on all operating systems or file systems. Additionally, manipulating file metadata could have legal or ethical implications, so use this script responsibly and ensure you have the right to modify the files.

get list of files from a folder and create them in new folder one by one but in random order until all the files are created in new folder

To achieve this, we'll write a Python script that:

1. Gets a list of all files from the source folder.
2. Randomizes the order of the files.
3. Creates each file in a new folder one by one in the randomized order.

Here's a script to accomplish this:

```python
import os
import shutil
import random

# Define the source and destination folders
source_folder = '/path/to/source/folder'
destination_folder = '/path/to/destination/folder'

# Create the destination folder if it doesn't exist
os.makedirs(destination_folder, exist_ok=True)

# Get the list of files from the source folder
files = os.listdir(source_folder)

# Shuffle the list of files to randomize the order
random.shuffle(files)

# Iterate over the shuffled list and copy each file to the destination folder
for filename in files:
    # Construct full file path
    source_file = os.path.join(source_folder, filename)
    destination_file = os.path.join(destination_folder, filename)

    # Copy the file from source to destination
    shutil.copy2(source_file, destination_file)

    # Print the file being copied for verification
    print(f"Copied {filename} to {destination_folder}")
```

How It Works

1. **Source and Destination Folders**: The script defines the paths to the source folder (where the original files are located) and the destination folder (where the files will be copied to).
2. **Creation the Destination Folder**: If the destination folder does not exist, it is created using `os.makedirs()`.
3. **Listing and Shuffling Files**: The list of files in the source folder is obtained using `os.listdir()` and then shuffled randomly using `random.shuffle()`.
4. **Copying Files**: The script iterates over the shuffled list of files and copies each file from the source folder to the destination folder using `shutil.copy2()`. This function is used to preserve the file metadata (such as modification times).

Usage

1. Replace `'/path/to/source/folder'` with the actual path to your source folder.
2. Replace `'/path/to/destination/folder'` with the path to your desired destination folder.

This script will copy all the files from the source folder to the destination folder in a randomized order. The `shutil.copy2()` function ensures that the original file's metadata is preserved.

when copying the created time and modified time should match with the system time

To ensure that the copied files in the destination folder have their creation and modification times set to the current system time, we can modify the script to explicitly set these times after copying each file. Since Python's `os.utime()` only modifies access and modification times, we'll use it to set both the modification and access times to the current time.

Here's an updated version of the script:

```python
import os
import shutil
import random
import time

# Define the source and destination folders
source_folder = '/path/to/source/folder'
destination_folder = '/path/to/destination/folder'

# Create the destination folder if it doesn't exist
os.makedirs(destination_folder, exist_ok=True)

# Get the list of files from the source folder
files = os.listdir(source_folder)

# Shuffle the list of files to randomize the order
random.shuffle(files)

# Current system time (as a timestamp)
current_time = time.time()

# Iterate over the shuffled list and copy each file to the destination folder
for filename in files:
    # Construct full file path
    source_file = os.path.join(source_folder, filename)
    destination_file = os.path.join(destination_folder, filename)

    # Copy the file from source to destination
    shutil.copy2(source_file, destination_file)

    # Set the access and modification times to the current system time
    os.utime(destination_file, (current_time, current_time))

    # Print the file being copied for verification
    print(f"Copied {filename} to {destination_folder} with current system time")
```

Explanation of Changes

1. **Current System Time**: We retrieve the current system time using `time.time()`, which returns the time in seconds since the epoch (January 1, 1970).
2. **Setting File Times**: After copying each file, we use `os.utime()` to set the access and modification times of the copied file to the current system time. The method takes a tuple `(atime, mtime)` representing the access time and modification time, respectively.

Usage

Replace the placeholder paths `'/path/to/source/folder'` and `'/path/to/destination/folder'` with your actual folder paths. The script will now copy the files to the destination folder and set both the creation and modification times to match the system time at the time of copying. Note that while `os.utime()` sets the access and modification times, not all systems or file systems may support changing the creation time explicitly.

use shutil.copy instead of shutil.copy2

Certainly! The `shutil.copy()` function is used to copy the contents of a file from one location to another but does not preserve metadata such as the original file's access and modification times. Since you want the copied files to have their creation and modification times set to the current system time, we'll use `shutil.copy()` and then set the times explicitly.

Here's the updated script:

```python
import os
import shutil
import random
import time

# Define the source and destination folders
source_folder = '/path/to/source/folder'
destination_folder = '/path/to/destination/folder'

# Create the destination folder if it doesn't exist
os.makedirs(destination_folder, exist_ok=True)

# Get the list of files from the source folder
files = os.listdir(source_folder)

# Shuffle the list of files to randomize the order
random.shuffle(files)

# Current system time (as a timestamp)
current_time = time.time()

# Iterate over the shuffled list and copy each file to the destination folder
for filename in files:
    # Construct full file path
    source_file = os.path.join(source_folder, filename)
    destination_file = os.path.join(destination_folder, filename)

    # Copy the file from source to destination
    shutil.copy(source_file, destination_file)

    # Set the access and modification times to the current system time
    os.utime(destination_file, (current_time, current_time))

    # Print the file being copied for verification
    print(f"Copied {filename} to {destination_folder} with current system time")
```

Key Points

1. **`shutil.copy()`**: This function copies the contents of the source file to the destination file. It does not copy metadata such as access and modification times.
2. **Setting File Times**: After copying the file, `os.utime()` is used to set both the access and modification times of the file to the current system time. This ensures that the copied files in the destination folder appear as newly created with the system's current time.

Usage

Replace the paths `'/path/to/source/folder'` and `'/path/to/destination/folder'` with the actual paths you are working with. The script will copy the files to the destination folder and set their creation and modification times to match the current system time at the time of copying.

add 1 sec delay between copy

To add a 1-second delay between copying each file, you can use the `time.sleep()` function. This function pauses the program's execution for the specified number of seconds.

Here's the updated script with the 1-second delay:

```python
import os
import shutil
import random
import time

# Define the source and destination folders
source_folder = '/path/to/source/folder'
```
